

# Awareness Growth with Bayesian Networks

July 13, 2023

*Wordcount (including footnotes): 8,475*

We examine different counterexamples to Reverse Bayesianism, a popular theory that addresses the problem of awareness growth. We agree with the general skepticism toward Reverse Bayesianism, but submit that the problem of awareness growth cannot be tackled in an algorithmic manner, because subject-matter, structural assumptions need to be made explicit and play a role in determining how probabilities should be updated in light of awareness growth. Thanks to their ability to express probabilistic dependencies, we illustrate how Bayesian networks can help to model awareness growth in the Bayesian framework.

## 1 Introduction

Learning is modeled in the Bayesian framework by the rule of conditionalization. This rule posits that the agent's new degree of belief in a proposition  $H$  after a learning experience  $E$  should be the same as the agent's old degree of belief in  $H$  conditional on  $E$ . That is,

$$P^E(H) = P(H|E),$$

where  $P()$  represents the agent's old degree of belief (before the learning experience  $E$ ) and  $P^E()$  represents the agent's new degree of belief (after the learning experience  $E$ ).

Both  $E$  and  $H$  belong to the agent's algebra of propositions. This algebra models the agent's awareness state, the propositions taken to be live possibilities. Conditionalization never modifies the algebra and thus makes it impossible for an agent to learn something they have never thought about. Even before learning about  $E$ , the agent must already have assigned a degree of belief to any proposition conditional on  $E$ . This picture commits the agent to the

1 specification of their ‘total possible future experience’ (Howson, 1976), as though learning was  
2 confined to an ‘initial prison’ (Lakatos, 1968).

3 But, arguably, the learning process is more complex than what conditionalization allows. Not  
4 only do we learn that some propositions under consideration are true or false, but we may also  
5 learn new propositions that we did not consider before. Or we may consider new propositions—  
6 without necessarily learning that they are true or false—and this change in awareness may  
7 in turn change what we already believe. How should this more complex learning process be  
8 modeled by Bayesianism? Call this the problem of awareness growth.

9 The algebra of propositions need not be so narrowly construed that it only contains proposi-  
10 tions that are presently under consideration. The algebra may also contain propositions which,  
11 though outside the agent’s present consideration, are still the object, perhaps implicitly, of  
12 certain dispositions to believe.<sup>1</sup> But even this expanded algebra will have to be revised sooner  
13 or later. The algebra of propositions could in principle contain anything that could possibly be  
14 conceived, expressed, thought of. Such a rich algebra would not need to change at any point,  
15 but this is an implausible model of ordinary agents with bounded resources such as ourselves.

16 Critics of Bayesianism and sympathizers alike have been discussing the problem of awareness  
17 growth under different names for quite some time, at least since the eighties. This problem arises  
18 in a number of different contexts, for example, new scientific theories (Chihara, 1987; Earman,  
19 1992; Glymour, 1980), language changes and paradigm shifts (Williamson, 2003), and theories  
20 of induction (Zabell, 1992). A proposal that has attracted considerable scholarly attention  
21 in recent years is Reverse Bayesianism (Bradley, 2017; Karni & Vierø, 2015; Wenmackers  
22 & Romeijn, 2016). The idea is to model awareness growth as a change in the algebra while  
23 ensuring that the proportions of probabilities of the propositions shared between the old and  
24 new algebra remain the same in a sense to be specified.

25 Let  $\mathcal{F}$  be the initial algebra of propositions and let  $\mathcal{F}^+$  be the algebra after the agent’s  
26 awareness state has grown. Both algebras contain the contradictory and tautologous propo-  
27 sitions  $\perp$  and  $\top$ , and they are closed under connectives such as disjunction  $\vee$ , conjunction  
28  $\wedge$  and negation  $\neg$ . Denote by  $X$  and  $X^+$  the subsets of these algebras that contain only basic  
29 propositions, namely those without connectives. **Reverse Bayesianism** posits that the ratio

---

<sup>1</sup>Roussos (2021) notes that, for the sake of clarity, the problem of awareness growth should only address propositions which agents are *truly* unaware of (say new scientific theories), not propositions that were temporarily forgotten or set aside. This is a helpful clarification to keep in mind, although the recent literature on the topic does not make a sharp distinction between true unawareness and temporary unawareness.

1 of probabilities for any basic propositions  $A$  and  $B$  in both  $X$  and  $X^+$ —the basic propositions  
2 shared by the old and new algebra—remain constant through the process of awareness growth:

$$\frac{P(A)}{P(B)} = \frac{P^+(A)}{P^+(B)},$$

3 where  $P()$  represents the agent's degree of belief before awareness growth and  $P^+()$  represents  
4 the agent's degree of belief after awareness growth.

5 Reverse Bayesianism is an elegant theory that manages to cope with a seemingly intractable  
6 problem. As the awareness state of an agent grows, the agent would prefer not to throw  
7 away completely the epistemic work they have done previously. The agent may desire to retain  
8 as much of their old degrees of beliefs as possible. Reverse Bayesianism provides a simple  
9 recipe to do that. It also coheres with the conservative spirit of Bayesian conditionalization  
10 which preserves the old probability distribution conditional on what is learned.

11 Unfortunately, Reverse Bayesianism does not deliver the intuitive results in all cases. There  
12 is no shortage of counterexamples against it in the recent philosophical literature (Mathani,  
13 2020; Steele & Stefánsson, 2021). In addition, attempts to extend traditional arguments in  
14 defense of Bayesian conditionalization to Reverse Bayesianism seem to hold little promise  
15 (Pettigrew, forthcoming). If the consensus in the literature is that Reverse Bayesianism is not  
16 the right theory of awareness growth, what theory (if any) should replace it?

17 Here we offer a diagnosis of what is wrong with Reverse Bayesianism and outline an  
18 alternative proposal. The problem of awareness growth—we hold—cannot be tackled in an  
19 algorithmic manner because subject-matter assumptions, both probabilistic and structural, need  
20 to be made explicit. So no adequate theory of awareness growth can be a purely formal theory.  
21 This does not mean, however, we should give up on probability theory altogether. Thanks  
22 to their ability to express probabilistic dependencies, Bayesian networks can help to model  
23 awareness growth in the Bayesian framework. We illustrate this claim as we examine different  
24 counterexamples to Reverse Bayesianism.

25 The plan for the paper is as follows. To set the stage for the discussion, Section 2 begins with  
26 two counter-examples to Reverse Bayesianism by Steele & Stefánsson (2021). One example  
27 targets awareness expansion and the other awareness refinement (more on the distinction soon).  
28 Section 3 models cases of awareness expansion using Bayesian networks. Section 4 further

1 illustrates the fruitfulness of this approach by looking at two counter-examples to Reverse  
2 Bayesianism by Mathani (2020). Section 5 turns to awareness refinement. Finally, Section 6  
3 outlines a general theory of awareness growth with Bayesian networks.

## 4 2 Steele and Stefánsson's Examples

5 In this section, we rehearse two of the counterexamples to Reverse Bayesianism by Steele &  
6 Stefánsson (2021). One example targets awareness expansion and the other awareness refine-  
7 ment. A precise definition of expansion can be tricky to provide, but a rough characterization  
8 will suffice for now. Suppose, as is customary, propositions are interpreted as sets of possible  
9 worlds, where the set of all possible worlds is the possibility space. Awareness expansion  
10 occurs when a new proposition is added to the algebra and its interpretation includes possible  
11 worlds not in the original possibility space. So the addition of the new proposition causes the  
12 possibility space to expand. By contrast, awareness refinement (roughly) occurs when the new  
13 proposition added to the algebra induces a more fine-grained partition of the possibility space.

14 The most straightforward case of *awareness expansion* occurs when you become aware  
15 of a new explanation for the evidence at your disposal which you had not considered before.  
16 This can happen in many fields of inquiry: medicine, law, science, everyday affairs. Here is a  
17 scenario by Steele & Stefánsson (2021):

18 FRIENDS: “Suppose you happen to see your partner enter your best friend’s house  
19 on an evening when your partner had told you she would have to work late. At  
20 that point, you become convinced that your partner and best friend are having  
21 an affair, as opposed to their being warm friends or mere acquaintances. You  
22 discuss your suspicion with another friend of yours, who points out that perhaps  
23 they were meeting to plan a surprise party to celebrate your upcoming birthday—a  
24 possibility that you had not even entertained.” [Sec. 5, Example 2]

25 Initially, the algebra contained the hypotheses ‘my partner and my best friend met to have an  
26 affair’ (*affair*) and ‘my partner and my best friend met as friends’ (*friends*). These were the  
27 only explanations you considered for the fact that your partner and your best friend met one  
28 night without telling you. But, when the algebra changes, a new hypothesis is added which you  
29 had not considered before: your partner and your best friends met to plan a surprise party for

1 your upcoming birthday (*surprise*).

2 This change in the algebra is not inconsequential. At first, the hypothesis *affair* seems more  
3 likely than *friends* because the former seems a better explanation than the latter for the secretive  
4 behavior of your partner and best friend.<sup>2</sup> But when the new hypothesis *surprise* is added,  
5 things change: *surprise* now seems a better explanation overall and thus more likely than  
6 *affair*. And since *surprise* implies *friends*, the latter must be more likely than *affair*. This  
7 conclusion violates Reverse Bayesianism since the ratio of the probabilities of *friends* and  
8 *affair* has changed before and after awareness expansion:

$$\frac{P(\textit{affair})}{P(\textit{friends})} > 1 \text{ but } \frac{P^+(\textit{affair})}{P^+(\textit{friends})} < 1.$$

9 Steele & Stefánsson note that a quick fix is available. It is reasonable to suppose that no  
10 change in the probabilities should occur so long as we confine ourselves to the old probability  
11 space. With this in mind, consider the following condition, called **Awareness Rigidity**:

$$P^+(A|T^*) = P(A),$$

12 where  $T^*$  corresponds to a proposition that picks out, from the vantage point of the new  
13 awareness state, the entire possibility space *before* the episode of awareness growth. Awareness  
14 rigidity posits that, once a suitable proposition  $T^*$  is identified, the old probability assignments  
15 remain unchanged conditional on  $T^*$ . In our running example,  $\neg\textit{surprise}$  is the suitable  
16 proposition  $T^*$ : *that* there was no surprise party in the making picks out the original possibility  
17 space. Conditional on  $\neg\textit{surprise}$ , no probability assignment should change, including the  
18 probability of *affair*. This is the intended result.

19 But this is not the end of the story. Steele & Stefánsson go on to show that Awareness  
20 Rigidity does not hold in other cases, what they call *awareness refinement*. As noted before,  
21 these are cases in which the new proposition induces a more fine-grained partition of the  
22 possibility space. Consider this scenario:

23 MOVIES: “Suppose you are deciding whether to see a movie at your local cinema.

24 You know that the movie’s predominant language and genre will affect your

---

<sup>2</sup>This assumes that the prior probabilities of the two hypotheses were not strongly skewed in one direction. If you were initially nearly certain your partner could not possibly have an affair with your best friend, the fact they behaved secretly or lied to you should not affect that much the probability of the two hypotheses.

1 viewing experience. The possible languages you consider are French and German  
2 and the genres you consider are thriller and comedy. But then you realise that,  
3 due to your poor French and German skills, your enjoyment of the movie will  
4 also depend on the level of difficulty of the language. Since it occurs to you that  
5 the owner of the cinema is quite simple-minded, you are, after this realisation,  
6 much more confident that the movie will have low-level language than high-level  
7 language. Moreover, since you associate low-level language with thrillers, this  
8 makes you more confident than you were before that the movie on offer is a thriller  
9 as opposed to a comedy.” (Steele & Stefánsson, 2021, sec. 5, Example 3)

10 You initially categorized movies by just language and genre, and then you refined your catego-  
11 rization by adding another variable, level of difficulty. Without considering language difficulty,  
12 you assigned the same probability to the hypotheses *thriller* and *comedy*. But learning that the  
13 owner was simple-minded made you think that the level of linguistic difficulty must be low and  
14 the movie most likely a thriller rather than a comedy (perhaps because thrillers are simpler—  
15 linguistically—than comedies). Since the probability of *thriller* goes up, this scenario violates  
16 (against Reverse Bayesianism) the condition  $\frac{P(\text{thriller})}{P(\text{comedy})} = \frac{P^+(\text{thriller})}{P^+(\text{Comedy})}$ . For the same reason, it also  
17 violates (against Awareness Rigidity) the condition  $P(\text{thriller}) = P^+(\text{thriller}|\text{thriller} \vee \text{comedy})$ ,  
18 where  $\text{thriller} \vee \text{comedy}$  is a proposition that picks out the entire possibility space.<sup>3</sup>

19 Some might object that the probability of *thriller* goes up, not because of awareness refine-  
20 ment, but because you learn that the owner is simple-minded. And if learning in the strict  
21 Bayesian sense—one modeled by conditionalization—takes place, it should be no surprise that  
22 some probabilities will change. Maybe so, but we will see that there are cases of awareness  
23 refinement that do not involve learning in the Bayesian sense and still violate Reverse Bayesian-  
24 ism and Awareness Rigidity (see Section 5). So, we should look for other principles that can  
25 better model the phenomenon of awareness growth.

26 Or should we, really? As will become clear, we believe that theorizing about awareness  
27 growth should be grounded in the subject-matter information underlying the scenario at hand.  
28 This subject-matter takes many forms. In FRIENDS, awareness expansion does not change  
29 the basic presupposition that someone’s behavior must have a reason. In MOVIES, awareness  
30 refinement does not change the fact that characteristics such as language, difficulty or genre

---

<sup>3</sup>Since MOVIES is a case of refinement, *thriller*  $\vee$  *comedy* picks out the entire possibility space both before and after awareness growth.

1 may influence one's decision to select a movie for showing rather than another. What is wrong  
2 with principles such as Reverse Bayesianism or Awareness Rigidity—we hold—is that they  
3 are purely formal. We need instead a formalism that can represent the relevant subject-matter  
4 information. In what follows, we illustrate how Bayesian networks can serve this purpose.

### 5 **3 Expansion with Bayesian Networks**

6 A Bayesian network is a compact formalism to represent probabilistic dependencies. It consists  
7 of a direct acyclic graph (DAG) accompanied by a probability distribution. The nodes in  
8 the graph represent random variables that can take different values. We will use 'nodes' and  
9 'variables' interchangeably. The nodes are connected by arrows, but no loops are allowed,  
10 hence the name 'direct acyclic graph'. A simple graph structure we will use repeatedly is the  
11 so-called *hypothesis-evidence idiom* (Fenton, Neil, & Lagnado, 2013):

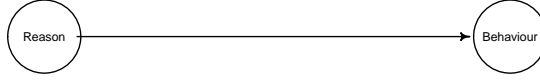

13 where  $H$  is the hypothesis node (upstream) and  $E$  the evidence node (downstream). If an  
14 arrow goes from  $H$  to  $E$ , the full probability distribution associated with the Bayesian network  
15 is defined by two probability tables.<sup>4</sup> One table defines the prior probabilities  $P(H = h)$  for  
16 all the states (or values) of  $H$ , and another table defines the conditional probabilities of the  
17 form  $P(E = e|H = h)$ , where uppercase letters represent the variables (nodes) and lower case  
18 letters represent the states (or values) of these variables. These two probability tables are  
19 sufficient to specify the full probability distribution. The other probabilities—say  $P(E = e)$ ,  
20  $P(H = h|E = e)$ , etc.—follow by simply applying the probability axioms. As needed, more  
21 complex graphical structures can also be used.

22 Bayesian networks are relied upon in many fields, but have been rarely deployed to model  
23 awareness growth (the exception is Williamson (2003)). We think instead they are a good  
24 framework for this purpose. Awareness growth can be modeled as a change in the graphi-  
25 cal network—nodes and arrows are changed, added or erased—as well as a change in the  
26 probability distribution from the old to the new network.

---

<sup>4</sup>A major point of contention in the interpretation of Bayesian networks is the meaning of the directed arrows. They could be interpreted causally—as though the direction of causality proceeds from the events described by the hypothesis to event described by the evidence—but they need not be; see footnote 17.

1 Recall the scenario FRIENDS from before. It can be modeled with the hypothesis-evidence  
 2 idiom. The graph can be made more perspicuous by labeling the downstream node ‘Behavior’  
 3 (the evidence or fact to be explained) and the upstream node ‘Reason’ (the explanation or  
 4 hypothesis about the cause of the behavior):

6 Initially, before awareness growth, the hypothesis node *Reason* takes only two states: *friends*  
 7 and *affair*. These two states are meant to be exclusive and exhaustive, so *affair* functions  
 8 as the negation of *friends*, and vice versa. After awareness growth—specifically, awareness  
 9 expansion—the two states are no longer exhaustive. A third state is added: *surprise*. So, in the  
 10 formalism we are using, expansion simply consists in the addition of an extra state to one of  
 11 the nodes of the network. The rest of the structure of the network remains intact.

12 Recall that the ratio of posterior probabilities of *friends* to *affairs* changed as a result of  
 13 awareness expansion. The fact that your partner and best friend met without telling you—call  
 14 this behavior *secretive*—initially made *affair* more likely than *friends*, but then the same fact  
 15 made *friends* more likely than *affair* after awareness growth. So, formally,

$$\frac{P(\text{Reason}=\text{affair}|\text{Behavior}=\text{secretive})}{P(\text{Reason}=\text{friends}|\text{Behavior}=\text{secretive})} > 1 \text{ but } \frac{P^+(\text{Reason}=\text{friends}|\text{Behavior}=\text{secretive})}{P^+(\text{Reason}=\text{affair}|\text{Behavior}=\text{secretive})} > 1.$$

16 Despite this change in posterior probabilities, it is plausible to assume that the likelihoods  
 17 do not change. Even after awareness expansion, the fact that your partner and best friend met  
 18 without telling you—*secretive*—makes better sense in light of *affair* compared to *friends*:

$$\frac{P(\text{Behavior}=\text{secretive}|\text{Reason}=\text{affair})}{P(\text{Behavior}=\text{secretive}|\text{Reason}=\text{friends})} = \frac{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{affair})}{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{friends})} > 1.$$

19 This equality holds even though the novel explanation *surprise* introduced during awareness  
 20 expansion makes better sense of the secretive behavior overall:<sup>5</sup>

$$\frac{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{surprise})}{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{affair})} > 1.$$

<sup>5</sup>Even though  $\frac{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{surprise})}{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{affair})} > 1$  and  $\frac{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{affair})}{P^+(\text{Behavior}=\text{secretive}|\text{Reason}=\text{friends})} > 1$ —so *affair* still makes better sense of the evidence than *friends* before and after awareness expansion—the posterior probability of *friends* is higher than *affair* after awareness expansion.

1 This analysis suggests a reformulation of conditions such as Reverse Bayesianism and  
 2 Awareness Rigidity. Instead of comparing posterior probabilities of hypotheses given the  
 3 evidence ( $P(H = h|E = e)$ ), we can compare which explanation or hypothesis makes better  
 4 sense of the evidence ( $P(E = e|H = h)$ ). So, for all values  $h, h'$  and  $e$  of upstream node  $H$  and  
 5 downstream node  $E$  in the old network, consider the following constraint:

$$\frac{P(E = e|H = h)}{P(E = e|H = h')} = \frac{P^+(E = e|H = h \& X \neq x^*)}{P^+(E = e|H = h' \& X \neq x^*)}, \quad (C)$$

6 where  $x^*$  is the new state added and  $X$  is the node (upstream or downstream) to which the new  
 7 state belongs, such as  $H = \text{surprise}$  in FRIENDS.

8 In words, the constraint says that one's old assessment of the relative plausibility of two  
 9 competing hypotheses in light of a fixed body of evidence should remain unchanged after  
 10 awareness expansion. Constraint (C) is a variant of Reverse Bayesianism that only applies to  
 11 conditional probabilities of the form  $P(E = e|H = h)$  for Bayesian networks of the form  $H \rightarrow E$ .  
 12 In addition, the constraint mimics Awareness Rigidity in that it ensures that the conditional  
 13 probabilities in question exclude the novel state  $X = x^*$ .<sup>6</sup>

14 How generally does constraint (C) apply besides examples such as FRIENDS? We put  
 15 forward the following *working hypothesis*:

16 If there is no change in the structure of the network, constraint (C) holds generally.

17 If there is a change in the structure of the network, constraint (C) will fail under  
 18 certain conditions (to be specified later).

19 Since expansion—as we have defined it—does not change the network structure, the constraint  
 20 should always hold for expansion.<sup>7</sup> We provide support for this claim in the next section.

---

<sup>6</sup>When the novel state is added to the upstream node  $H$ , the condition  $X \neq x^*$  is redundant. We will see later cases in which the novel state is added to the downstream node  $E$ , and here the condition is not redundant.

<sup>7</sup>It is crucial that the new hypothesis or explanation does not change the existing structure of the network. Consider this example. You are wondering which horse will win the race. You have done a careful study of past performances under different conditions and concluded that Red is more likely to win than Green. But you have not considered the possibility that Grey would run. If Grey does run, it will have a greater chance of winning than the others, but will also make—for some odd reason—Green a much better racer than Red. So the odds that Green will win compared to Red should now be higher. Here, the new hypothesis introduces novel information that was not known before, say that the participation of Grey would weaken Red's performance and strengthen Green's performance. So the network should be changed in two ways: first, a new state should be added to the outcome node (Green wins; Red wins; Grey wins); and second, a new node should be added modeling the fact that Grey is participating and its participation affects Red's and Green's performance.

## 4 Mathani's Examples

To acquire a firmer grasp on constraint (C), we now examine a couple of examples by Mathani (2020). They are intended as counterexamples to Reverse Bayesianism, as well as a challenge to the distinction between expansion and refinement. When modeled with Bayesian networks, however, Mathani's examples are straightforward cases of awareness expansion.

The first example goes like this.

TENANT: You are staying at Bob's flat which he shares with the landlord. In the morning you hear singing coming from the shower. Initially, you thought the singer could either be the landlord or Bob, the tenant. Then you come to the realization that a third person could be the singer, another tenant.

The possibility that there could be a third person in the shower—besides Bob or the landlord—is a novel explanation for why you hear singing in the shower. So TENANT seems to be a standard case of expansion like FRIENDS. At the same time, this scenario is a bit more complicated. The expansion in awareness goes along with an interesting conceptual shift. Before awareness expansion, that Bob is in the shower and that a tenant is in the shower are equivalent descriptions (you thought there was only one tenant). After the expansion, this equivalence breaks down.

As Mathani shows, this scenario challenges Reverse Bayesianism. For it is natural to assign  $1/3$  to *landlord*, *bob* and *other* after awareness growth, and  $1/2$  to *landlord* and *bob* before awareness growth. That someone is singing in the shower is evidence that someone must be in there, but without any more discriminating evidence, each person should be assigned the same probability. Consequently, a probability of  $2/3$  should be assigned to *tenant* after awareness growth (since Bob or someone else could be the tenant), but only  $1/2$  before (since only Bob could be the tenant). On this picture, the proportion of *landlord* to *tenant* changes from 1:1 (before awareness growth) to 1:2 (after awareness growth).<sup>8</sup>

One could resist the challenge. For recall that Reverse Bayesianism only applies to basic propositions, which we defined earlier as propositions without connectives. So a possible fix is

---

<sup>8</sup>This scenario need not challenge Awareness Rigidity. Much depends on the choice of the proposition  $T^*$  that picks out, from the vantage point of the new awareness state, the old possibility space prior to awareness growth. The proposition  $landlord \vee bob$  does the job. For  $P^+(landlord|landlord \vee bob)$  and  $P^+(bob|landlord \vee bob)$  should both equal  $1/2$ , and thus  $P^+(other|landlord \vee bob) = 0$ , but this does not mean that  $P^+(other|landlord \vee tenant)$  should equal zero. This is the intended result.

1 to adopt the following principle: if two propositions happen to be equivalent relative to some  
 2 awareness state, they cannot be both considered basic. In TENANT, since *bob* and *tenant* are  
 3 initially equivalent descriptions of the same state of affairs, they would not be considered both  
 4 basic propositions. If only *bob* is considered basic, along with *landlord*, then the proportion of  
 5 the probability of *bob* and *landlord* would remain the same during awareness growth, but not  
 6 the proportion of the probabilities of *tenant* and *landlord*. This yields the intuitive result.

7 But why should some propositions considered basic and not others? There is no obvious  
 8 way to draw the line between the two. Still, this discussion alerts us to the fact that a difference  
 9 exists between propositions like *bob* and those like *tenant*. The latter describes a role that  
 10 different people could play besides Bob. Bayesian networks can help to model the person/role  
 11 distinction, as follows:

13 This subject-matter information—the distinction between people and the role they play—remain  
 14 fixed throughout the process of awareness expansion. What changes is how the details are filled  
 15 in. Initially, the upstream node *Person* has two possible states, representing who could be in the  
 16 bathroom singing: *landlord-person* and *bob*.<sup>9</sup> The downstream node *Role* has also two values,  
 17 *landlord* and *tenant*. After your awareness grows, the upstream node *Person* should now have  
 18 one more possible state, *other*. Crucially, note that since TENANT is a case of expansion by  
 19 our definition—a state was added to a node—constraint (C) should hold. This is precisely what  
 20 happens. After all, the conditional probabilities  $P(\text{Role} = \text{landlord} | \text{Person} = \text{landlord-person})$   
 21 and  $P(\text{Role} = \text{landlord} | \text{Person} = \text{bob})$  do not change after awareness growth (see Table 1).

22 It is now time to test the tenability of constraint (C) in cases of awareness expansion further.  
 23 So far we only considered cases of expansion in which a new state was added to an *upstream*  
 24 node. In FRIENDS, a state was added to the upstream node *Reason*, and in TENANT, a state  
 25 was added to the upstream node *Person*. What if the new state was added to a downstream  
 26 node? To this end, consider another example by Mathani:

27 COIN: "You know that I am holding a fair ten pence UK coin which I am about  
 28 to toss. You have a credence of 0.5 that it will land *heads*, and a credence of 0.5

<sup>9</sup>To simplify things, the assumption here is that the evidence of singing has already ruled out the possibility that no one would be in the shower. In principle, the network should be more complex and contain another node for the evidence to be explained (the fact of singing in the shower), as follows: *Singing*  $\leftarrow$  *Person*  $\rightarrow$  *Role*.

$P(\text{Role} \text{Person})$		$\text{Person}$	
$\text{Role}$	$\text{tenant}$	$\text{landlord-person}$	$\text{bob}$
	$\text{landlord}$	0	1
	TOTAL	1	0
		1	1

Table 1: The table displays a plausible probability distribution for the TENANT scenarios. Constraint (C) is met.

1 that it will land *tails*. You think that the tails side always shows an engraving of a  
2 lion. So you also have a credence of 0.5 that it will land with the lion engraving  
3 face-up (*lion*): relative to your state of awareness *tails* and *lion* are equivalent....  
4 Now let's suppose that you somehow become aware that occasionally ten pence  
5 coins have .... an engraving of Stonehenge on the tails side (*stonehenge*)."

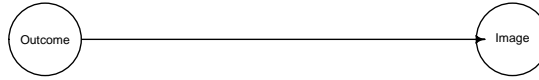

6 The propositions *tails* and *lion* are equivalent prior to awareness growth. Suppose you initially  
7 gave *tails* and *lion* the same credence. If they are basic propositions, Reverse Bayesianism  
8 would require that their relative probabilities should stay the same after awareness grow. The  
9 same is true of *heads* and *tails*. But since *lion* and *stonehenge* are incompatible and the latter  
10 entails *tails*, you should have  $P^+(\text{stonehenge}) = 0$ , an undesirable conclusion.

11 Mathani observes that this scenario blurs the distinction between expansion and refinement.  
12 For one thing, COIN seems a case of refinement. The space of possibilities is held fixed—the  
13 coin could come up heads or tails—but the options for tails are further refined, for tails could  
14 be *lion* or *stonehenge*. On the other hand, a new possibility has been added after awareness  
15 growth, namely *stonehenge*, which had not been considered before. This would indicate that  
16 COIN is a case of expansion.<sup>10</sup>

<sup>10</sup>This ambiguity makes it difficult to settle whether the scenario is a challenge for Awareness Rigidity. If

1 These difficulties disappear if the scenario is modeled using Bayesian networks. The  
 2 definition of awareness expansion we have been working with is simple: whenever a new state  
 3 is added to one of the nodes in the network, awareness expansion takes place. Each node, with  
 4 its range of states, characterizes an exhaustive partition of the possibility space. Whenever a  
 5 new state is added to a node, the partition associated with the node expands. By the definition  
 6 of expansion just given, COIN counts as a case of expansion.

7 The scenario can be modeled by this familiar graph structure:

9 The upstream node *outcome* has two states, *tails* and *heads*. These two states remain the same  
 10 throughout. What changes are the states associated with the *image* node downstream. Before  
 11 awareness growth, the node *image* has two states: *lions* and *heads-image*.<sup>11</sup> You assume that  
 12 *Image = lions* is true if and only if *Outcome = tails* is true. Then, you come to the realization  
 13 that the imagines for tails could include a lion or a stonehenge engraving. So, after awareness  
 14 growth, the node *Image* contains three states: *lion*, *stonehenge* and *heads-image*.

15 To some extent, COIN has the same structure as TENANT—they are modeled by the same  
 16 networks structure—but there is an important asymmetry. In COIN, the states of the upstream  
 17 node remain fixed while a new state is added to the downstream node. In TENANT, the opposite  
 18 happens: the states of the downstream node remain fixed, while a new state is added to the  
 19 upstream node. Specifically, after awareness expansion, no new state is added to upstream  
 20 node *Outcome*, but an additional state, *other*, is added to the downstream node *Person*.

21 So what about constraint (C)? It is easy to check that it is satisfied. Conditional probabil-  
 22 ities such as  $P(\text{Image} = \text{lions} | \text{Outcome} = \text{tails})$  or  $P(\text{Image} = \text{lions} | \text{Outcome} = \text{heads})$  remain  
 23 unchanged after awareness growth given the condition  $\text{Image} \neq \text{stonehenge}$ . Initially,  $\text{Image} =$   
 24 *lions* is true if and only if  $\text{Outcome} = \text{tails}$  is true. So,  $P(\text{Image} = \text{lions} | \text{Outcome} = \text{tails})$   
 25 equals one, but it must also be that  $P^+(\text{Image} = \text{lions} | \text{Outcome} = \text{tails} \ \& \ \text{Image} \neq \text{stonehenge})$   
 26 equals one. More generally, plausible probability distributions for the Bayesian networks

---

the scenario is a case of refinement,  $\text{heads} \vee \text{tails}$  would pick out the entire possibility space even before awareness growth. If so, by Awareness Rigidity,  $P^+(\text{tails} | \text{heads} \vee \text{tails})$  and  $P^+(\text{lion} | \text{heads} \vee \text{tails})$  should both equal  $1/2$  since these were their probabilities before awareness growth. But these assignments would force  $P^+(\text{stonehenge} | \text{heads} \vee \text{tails})$  to zero. To avoid this odd result for awareness Rigidity, one might argue that  $\text{heads} \vee \text{tails}$  picks out a possibility space larger than the old one, because it also includes the possibility of *stonehenge*. But arguably  $\text{heads} \vee \text{tails}$  should not pick out a larger possibility space.

<sup>11</sup>The heads side must have some image, not specified in the scenario.

Table 2: Table displays a plausible probability distribution for the COIN scenario. Constraint (C) is met.

1 associated with the scenario COIN is displayed in Table 2. Constraint (C) is never violated.

2 All in all, examples in the literature that count as cases of expansion under our definition—

3 that is, a state is added to a network without changes in the network structure—obey constraint

4 (C). This provides good support for the first part of our working hypothesis: if there is no

5 change in the structure of the network, constraint (C) holds generally (see end of Section 3). In

6 this sense, the constraint has outperformed both Reverse Bayesianism and Awareness Rigidity.

7 But our objective here is not to replace one formal constraint with another. As noted in the

8 introduction, we think that the phenomenon of awareness growth in its generality cannot be

9 modeled in a purely formal matter. The success of constraint (C) relies on the right network

10 structure. How the networks should be built is based on our subject-matter knowledge—for

11 example, that people’s behavior must have a reason; that multiple peoples can play different

12 roles; or that heads and tails can be associated with different specific engravings. Constraint (C)

13 holds when this subject-matter knowledge does not change. However, sometimes awareness

14 growth may bring in new subject-matter knowledge and require changes to the structure of the

15 network. This is our next topic.

## 16 5 Refinement with Bayesian Networks

17 To see how the network structure itself may require modifications, we turn now from cases of

18 expansion to cases of refinement. In the framework of Bayesian networks, expansion consists in

1 adding states to existing nodes in the network. Refinement, instead, can be modeled by adding  
2 nodes to the network without adding any new state to existing nodes. Intuitively, refinement  
3 takes place when an epistemic agent acquires a more-fine grained picture of the situation.

4 Although there is no shortage of counterexamples to Reverse Bayesianism when it comes  
5 to awareness refinement, we will use our own. Recall that MOVIES—the refinement-based  
6 counterexample to Reverse Bayesianism by Steele & Stefánsson in Section 2—suffered from a  
7 possible objection. The example contained awareness refinement paired with a standard case  
8 of Bayesian learning by conditionalization. We will work with our own example which can be  
9 more clearly interpreted as mere awareness refinement. So consider this scenario:

10 LIGHTING: You have evidence that favors a certain hypothesis, say a witness saw  
11 the defendant around the crime scene. You give some weight to this evidence.

12 In your assessment, that the defendant was seen around the crime scene (your  
13 evidence) raises the probability that the defendant was actually there (your hypoth-  
14 esis). But now you ask, what if it was dark when the witness saw the defendant?

15 In light of your realization that it could have been dark, you wonder whether (and  
16 if so how) you should change the probability that you assigned to the hypothesis  
17 that the defendant was around the crime scene.

18 As your awareness grows, you do not learn anything specific about the lighting conditions,  
19 neither that they were bad nor that they were good. You simply wonder what they were,  
20 a variable you had previously not considered.<sup>12</sup> Something has changed in your epistemic  
21 state—you have a more fine-grained assessment of what could have happened—but it is not  
22 clear what you should do in this scenario. Since the lighting conditions could have been bad but  
23 could also have been good, perhaps you should just stay put until you learn something more.

24 We now illustrate how Bayesian networks helps to model what is going on in LIGHTING.  
25 The starting point of our analysis is the usual hypothesis-evidence idiom, repeated below:

27 Since you trust the evidence, you think that the evidence is more likely under the hypothesis

---

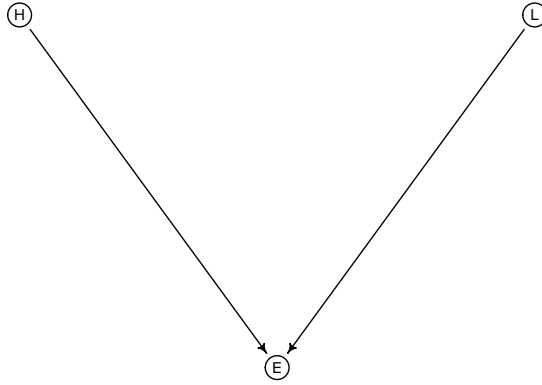

<sup>12</sup>The process of awareness growth in LIGHTING adds only one extra variable, lighting conditions, while MOVIES adds two extra variables, language difficulty and whether the owner is simple-minded or not. Further, MOVIES contains a clear-cut case of Bayesian updating, that the owner *is* simple-minded. This is not so in LIGHTING. Strictly speaking, you are learning that it is *possible* that the lighting conditions were bad. However, you are not conditioning on the proposition ‘the lighting conditions were bad’ or ‘the lighting conditions were good’. So you are not learning about the lighting conditions in the sense of Bayesian updating.

1 that the defendant was present at the crime scene than under the alternative hypothesis:

$$P(E=seen|H=present) > P(E=seen|H=absent)$$

2 The inequality is a qualitative ordering of how plausible the evidence is in light of competing  
3 hypotheses. By the probability calculus, the evidence raises the probability of  $H=present$ .

4 Now, as you wonder about the lighting conditions, the graph should be amended:

5  
6 where the node  $L$  can have two values,  $L=good$  and  $L=bad$ . What is going on here? Initially,  
7 you thought that the perceptual experience of the witness (node  $E$ ) was causally affected by the  
8 state of the whereabouts of the defendants (node  $H$ ). But, as your awareness growth, you realize  
9 that the witness' experience may also be caused by the environmental condition surrounding  
10 the experience itself, say the lighting conditions (node  $L$ ). So there are now two incoming  
11 arrows into node  $E$ . In addition, commonsense as well as psychological findings suggest that  
12 when the visibility deteriorates, people's ability to identify faces worsen. So a plausible way to  
13 modify your assessment of the evidence is as follows:

$$P^+(E=seen|H=present \wedge L=good) > P^+(E=seen|H=absent \wedge L=good)$$

14

$$P^+(E=seen|H=present \wedge L=bad) = P^+(E=seen|H=absent \wedge L=bad)$$

15 In words, if the lighting conditions were good, you still trust the evidence like you did before  
16 (first line), but if the lighting conditions were bad, you regard the evidence as no better than  
17 chance (second line).

18 Despite the change in awareness, you have not learned anything in the strict sense. Your  
19 new stock of evidence does not contain neither the information that the lighting conditions

1 were bad nor that they were good. But the Bayesian network structure that represents your  
 2 epistemic state is now more fine-grained. The network contains the new variable  $L$  which it  
 3 did not contain prior to the episode of awareness growth. In addition—and this is the crucial  
 4 point—the new variable bears certain *structural relationships* with the variables  $H$  and  $E$ . The  
 5 graphical network represents a direct probabilistic dependency between the lighting conditions  
 6  $L$  and the witness sensory experience  $E$ , but does not allow for any direct dependency between  
 7 the lighting conditions and the fact that the defendant was (or was not) at the crime scene. This  
 8 captures our causal intuitions about the scenario: the lighting conditions do affect what the  
 9 witness could see, but do not directly affect what the defendant might have done.

10 This model of the underlying causal structure can now guide us to decide whether our  
 11 revised version of Reverse Bayesianism, what we called constraint (C), holds in this scenario.  
 12 Specifically, we need to assess whether the following holds:

$$\frac{P(E = \text{seen} | H = \text{present})}{P(E = \text{seen} | H = \text{absent})} = \frac{P^+(E = \text{seen} | H = \text{present})}{P^+(E = \text{seen} | H = \text{absent})}.$$

13 The question here is whether you should assess the evidence at your disposal—that the witness  
 14 saw the defendant at the crime scene—any differently than before.<sup>13</sup> As noted earlier, without  
 15 a clear model of the scenario, it might seem that you should simply stay put. But, in changing  
 16 the probability function from  $P()$  to  $P^+()$ , it would be quite a coincidence if this were true. In  
 17 our example, many possible probability assignments violate this equality. To see this is tedious,  
 18 so we relegate the formal argument to a footnote.<sup>14</sup> Informally, if before awareness growth

<sup>13</sup>Note that since no new state was added to an existing node, the condition  $X \neq x^*$  in constraint (C) (where  $x^*$  is the new state added to an existing node  $X$ ) is redundant here.

<sup>14</sup>By the law of total probability, the right hand side of the equality in (C) should be expanded, as follows:

$$\frac{P^+(E = e | H = h)}{P^+(E = e | H = h')} = \frac{P^+(E = \text{seen} \wedge L = \text{good} | H = \text{present}) + P^+(E = \text{seen} \wedge L = \text{bad} | H = \text{present})}{P^+(E = \text{seen} \wedge L = \text{good} | H = \text{absent}) + P^+(E = \text{seen} \wedge L = \text{bad} | H = \text{absent})}.$$

For concreteness, let's use some numbers:

$$P(E = \text{seen} | H = \text{present}) = P^+(E = \text{seen} | H = \text{present} \wedge L = \text{good}) = .8$$

$$P(E = \text{seen} | H = \text{absent}) = P^+(E = \text{seen} | H = \text{absent} \wedge L = \text{good}) = .4$$

$$P^+(E = \text{seen} | H = \text{present} \wedge L = \text{bad}) = P^+(E = \text{seen} | H = \text{absent} \wedge L = \text{bad}) = .5.$$

$$P^+(L = \text{bad}) = P^+(L = \text{good}) = .5.$$

So the ratio  $\frac{P(E = \text{seen} | H = \text{present})}{P(E = \text{seen} | H = \text{absent})}$  equals 2. After the growth in awareness, the ratio  $\frac{P^+(E = \text{seen} | H = \text{present})}{P^+(E = \text{seen} | H = \text{absent})}$  will drop to  $\frac{.65}{.45} \approx 1.44$ . The calculations here rely on the dependency structure encoded in the Bayesian network (see starred step below).

$$\begin{aligned} P^+(E = \text{seen} | H = \text{present}) &= P^+(E = \text{seen} \wedge L = \text{good} | H = \text{present}) + P^+(E = \text{seen} \wedge L = \text{bad} | H = \text{present}) \\ &= P^+(E = \text{seen} | H = \text{present} \wedge L = \text{good}) \times P^+(L = \text{good} | H = \text{present}) \end{aligned}$$

1 you thought the evidence favored the hypothesis  $H=present$  to some extent, after the growth in  
2 awareness, the evidence is likely to appear less strong. Thus, constraint (C) will be violated.<sup>15</sup>

3 Still, it is crucial that this result only holds given specific subject-matter assumptions.  
4 Constraint (C) holds in other, structurally different cases of refinement. Consider this scenario:

5 VERACITY: A witness saw that the defendant was around the crime scene and  
6 you initially took this to be evidence that the defendant was actually there. But  
7 then you worry that the witness might be lying or misremembering what happened.  
8 Perhaps, the witness was never there, made things up or mixed things up. Should  
9 you reassess the evidence at your disposal? If so, how?

10 This scenario might seem no different from LIGHTING. The realization that lighting could be  
11 bad should make you less confident in the truthfulness of the sensory evidence. And the same  
12 conclusion should presumably follow from the realization that the witness could be lying. But,  
13 upon closer scrutiny, running the two scenarios together turns out to be a mistake.

14 The evidence at your disposal in LIGHTING is the sensory evidence—the experience of  
15 seeing—and the possibility of bad lighting does affect the quality of your visual experience.

---

$$\begin{aligned}
 &+ P^+(E=seen|H=present \wedge L=bad) \times P^+(L=bad|H=present) \\
 &=^* P^+(E=seen|H=present \wedge L=good) \times P^+(L=good) \\
 &+ P^+(E=seen|H=present \wedge L=bad) \times P^+(L=bad) \\
 &= .8 \times .5 + .5 \times .5 = .65
 \end{aligned}$$

$$\begin{aligned}
 P^+(E=seen|H=absent) &= P^+(E=seen \wedge L=good|H=absent) + P^+(E=seen \wedge L=bad|H=absent) \\
 &= P^+(E=seen|H=absent \wedge L=good) \times P^+(L=good|H=absent) \\
 &+ P^+(E=seen|H=absent \wedge L=bad) \times P^+(L=bad|H=absent) \\
 &=^* P^+(E=seen|H=absent \wedge L=good) \times P^+(L=good) \\
 &+ P^+(E=seen|H=absent \wedge L=bad) \times P^+(L=bad) \\
 &= .4 \times .5 + .5 \times .5 = .45
 \end{aligned}$$

This argument can be repeated with many other numerical assignments.

<sup>15</sup>Reverse Bayesianism, in its original formulation, is also violated since the ratio of the probabilities of  $H=present$  to  $E=seen$ , before and after awareness growth, has changed:

$$\frac{P^{E=seen}(H=present)}{P^{E=seen}(E=seen)} \neq \frac{P^{+,E=seen}(H=present)}{P^{+,E=seen}(E=seen)},$$

where  $P^{E=seen}()$  and  $P^{+,E=seen}()$  represent the agent's degrees of belief, before and after awareness growth, updated by the evidence  $E=seen$ . The scenario also violates Awareness Rigidity which requires that  $P^+(A|T^*) = P(A)$ , where  $T^*$  corresponds to a proposition that picks out, from the vantage point of the new awareness state, the entire possibility space before the episode of awareness growth. In LIGHTING, however,  $T^*$  does not change, so Awareness Rigidity would require that  $P^+(A) = P(A)$ , and instead in the scenario, we have

$$P^+(H=present|E=seen) \neq P(H=present|E=seen).$$

1 So, if lighting was indeed bad, this would warrant lowering your confidence in the truthfulness  
2 of the visual experience. But the possibility of lying in VERACITY does not affect the quality  
3 of the visual experience; it only affects the quality of the *reporting* of that experience. So, if  
4 the witness did lie, this would not warrant lowering your confidence in the truthfulness of the  
5 visual experience, only in the truthfulness of the reporting. The distinction between the visual  
6 experience and its reporting is crucial here. Bayesian networks help to model this distinction  
7 precisely, and then see why LIGHTING and VERACITY are structurally different.

8 The graphical network should initially look like the initial DAG for LIGHTING, consisting  
9 of the hypothesis node  $H$  upstream and the evidence node  $E$  downstream. As your awareness  
10 grows, the graphical network should be updated by adding another node  $R$  further downstream:

12 As before, the hypothesis node  $H$  bears on the whereabouts of the defendant and has two values,  
13  $H=present$  and  $H=absent$ . Note the difference between  $E$  and  $R$ . The evidence node  $E$  bears  
14 on the visual experience had by the witness. The reporting node  $R$ , instead, bears on what the  
15 witness reports to have seen. The chain of transmission from ‘visual experience’ to ‘reporting’  
16 may fail for various reasons, such as lying or misremembering.

17 In VERACITY, the conditional probabilities,  $P(E = e|H = h)$  should be the same as  $P^+(E =$   
18  $e|H = h)$  for any values  $e$  and  $h$  of the variables  $H$  and  $E$  that are shared before and after  
19 awareness growth. In comparing the old and new Bayesian network, this equality falls out from  
20 their structure, as the connection between  $H$  and  $E$  remains unchanged. Thus, constraint (C) is  
21 perfectly fine in scenarios such as VERACITY.<sup>16</sup>

22 Where does this leave us? Refinement cases that might at first appear similar can be  
23 structurally different in important ways, and this difference can be appreciated by looking at  
24 the Bayesian networks used to model them. In modeling VERACITY, the new node is added  
25 downstream, while in modeling LIGHTING, it is added upstream. This difference affects how

---

<sup>16</sup>This does not mean that the assessment of the probability of the hypothesis  $H=present$  should undergo no change. If you worry that the witness could have lied, this should presumably make you less confident about  $H=present$ . To accommodate this intuition, VERACITY can be interpreted as a scenario in which an episode of awareness refinement takes place together with a form of retraction. At first, after the learning episode, you update your belief based on the *visual experience* of the witness. But after the growth in awareness, you realize that your learning is in fact limited to what the witness *reported* to have seen. The previous learning episode is retracted and replaced by a more careful statement of what you learned: instead of conditioning on  $E=seen$ , you should condition on what the witness reported to have seen,  $R=seen-reported$ . This retraction will affect the probability of the hypothesis  $H=present$ .

1 probability assignments should be revised. Since the conditional probabilities associated with  
2 the upstream nodes are unaffected, constraint (C) is satisfied in VERACITY. By contrast, since  
3 the conditional probabilities associated with the downstream node will often have to change,  
4 the constraint fails in LIGHTING.

## 5 **6 Towards a general theory**

6 The moral of our discussion is that that subject-matter assumptions—in the case of LIGHTING  
7 and VERACITY, causal assumptions—about how we conceptualize a specific scenario are  
8 the guiding principles for how we should update the probability function through awareness  
9 growth, not formal principles like Reverse Bayesianism, Awareness Rigidity or even constraint  
10 (C). From the examples we have considered, Bayesian networks appear to be the right formal  
11 tools to model these subject-matter assumptions.

12 We conclude by sketching a more general recipe. The first step is to draw a direct acyclic  
13 graph  $\mathcal{G}$  that expresses the probabilistic dependencies between the variables (and their relative  
14 states) *before* awareness growth. This graph represents the material structural assumptions,  
15 based on commonsense, semantic stipulations or causal dependency.<sup>17</sup> The next step is to  
16 decide what changes to the graphical structure  $\mathcal{G}$  must be made to adequately model awareness  
17 growth. In general, awareness growth will require either to add states to the existing nodes  
18 (expansion) or to modify the structure of the network (refinement).

19 Suppose awareness growth is modeled by adding a state  $x^*$  to an existing node  $X$  in the  
20 network. Then, the existing probability tables in which  $X$  occurs should be modified to  
21 accommodate the new value  $x^*$  of  $X$ . Specifically, the probability table for  $X$  should be  
22 modified, as well as the probability tables for the children nodes of  $X$ . Constraint (C)—or a  
23 suitable generalization—will guide how to change the probability tables and define the new  
24 probability distribution.

25 Suppose instead awareness growth is modeled by adding a new node  $X$  to the network, where  
26 the addition of the new node only requires drawing additional arrows that connect the new  
27 node to existing nodes. There are different cases to distinguish here. In scenarios such as  
28 VERACITY and LIGHTING, the new nodes  $X$  is either added downstream of an existing node or

---

<sup>17</sup>Arrows in Bayesian networks are often taken to represent causal relationships, but other interpretations exist. Schaffer (2016) discusses an interpretation in which arrows represent grounding relations rather than causality.

1 downstream. A more complex case is one in which the new node is downstream relative to  
 2 multiple existing nodes (common effect) or upstream relative to both (common cause). In these  
 3 cases, either a new probability table should be added for  $X$  (when  $X$  is added downstream to  
 4 multiple existing nodes) or existing probability tables in which  $X$  occurs should be suitably  
 5 modified (when  $X$  is added upstream relative to multiple existing nodes). A more complicated  
 6 case still is one in which the new node  $X$  is both downstream (relative to an existing node  $A$ ,  
 7 or multiple such nodes) and upstream (relative to another existing node  $B$ , or multiple such  
 8 nodes).<sup>18</sup> In this case, a new probability table must be added for  $X$  and existing ones must be  
 9 modified.

10 We emphasize that this procedure is only partly algorithmic. A key role play the background  
 11 information that is formalized in the structure of the Bayesian network before and after  
 12 awareness growth. This procedure implements a conservative constraint by which minimal  
 13 changes are made to the old probability distribution. The changes are usually localized to the  
 14 probability tables of the node  $X$  and the children of node  $X$ . Following well-known properties  
 15 of Bayesian networks, these localized changes are justified on the basis of the dependencies  
 16 structure among the nodes in the old and new network.<sup>19</sup>

<sup>18</sup>For example, initially you thought that gender ( $G$ ) had an effect on graduate admission decision ( $D$ ). The aggregate data available indicate that women are less likely to be admitted to graduate schools. So the initial graph looks like this:  $G \rightarrow D$ . You then hypothesize that, since schools ( $S$ ) make decision about admission, not the university as a whole, there might an alternative path from  $G$  to  $D$ . Perhaps, women happen to prefer departments that have lower admission rates. So a new path must be added to the graph:  $G \rightarrow S \rightarrow D$ .

<sup>19</sup>The theory of Bayesian networks ensure that a variable  $X$  is independent from all other variables conditional on its so-called Markov blanket (which includes the parent and children nodes of  $X$ , as well as the parents of the children of  $X$ ).
